CYBER SITH'S WHITE TEAM DOCUMENTATION

URBANDALE HIGH SCHOOL: TEAM 4

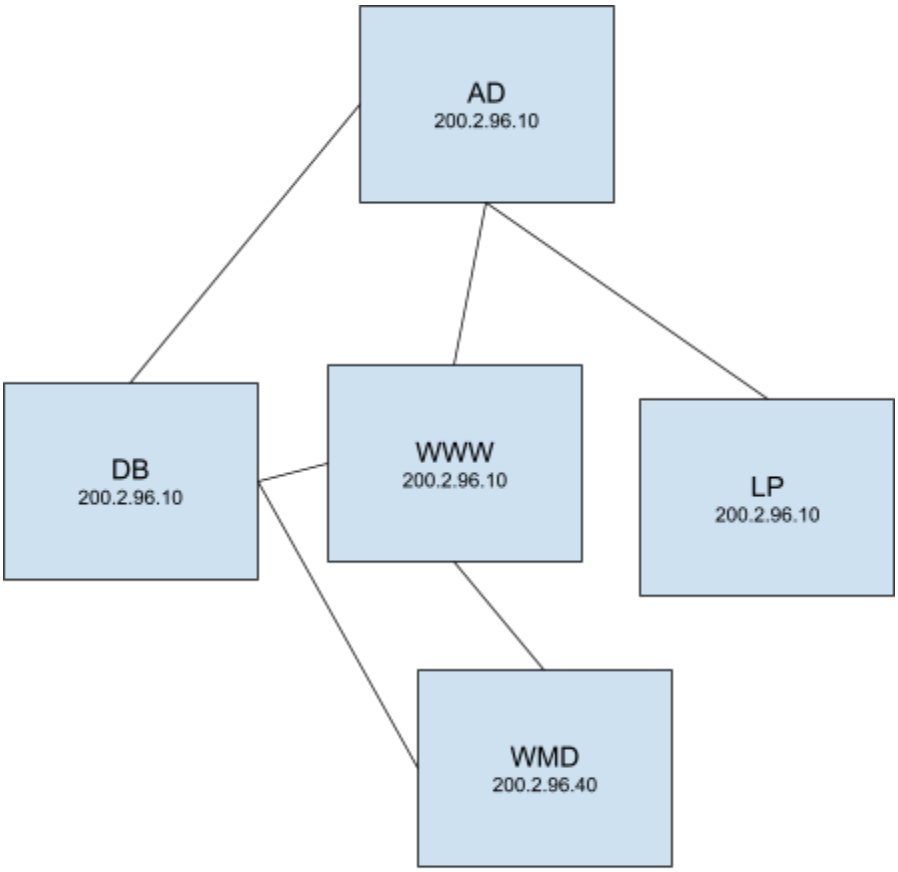
Written by Ethan Guild

Overview Of Public Servers

Server Name	IP Address	Purpose
Active Directory (ad)	200.2.96.10	Manages communications between all machines on the server.
Website (www)	200.2.96.20	Host the company's website and green users
Label Printer (lp)	200.2.96.30	Creates labels for outgoing orders and holds information
Warehouse Management System (wms)	200.2.96.40	Works the backend for www and performs necessary manufacturing operations for the company
Database (db)	200.2.96.50	Stores and manages information from www and wms

Overall this is a system designed to manufacture so the communications and function of these servers is pretty basic. The important connections were highlighted but will be elaborated later in the next section.

Network Topoligy



Given the connections between these servers there's a note that was done to secure our services from hackers. The active directory in particular is especially important for securing as it serves as a bridge and connection between most of the rest of the servers. All servers have undergone hardening to protect and narrow the connections between their fellow servers.

Network and Security

Traffic Security: All linux servers have undergone the implementation of firewall rules, the attempt to restrict traffic to the bare minimum in order to narrow any surface of attack.

Windows Security: Both windows servers have had numerous software updates and maintenance to ensure that they are running as properly and securely as possible. Many windows pelicans were implemented and updated in order to secure the network on these machines.

Files: All machines provided were thoroughly searched and cleansed as seen necessary to remove harmful or unnecessary applications on our servers. This, ideally, prevents possible exploits while also further reducing the surface or possibility of attack.

Monitoring: Nmap and similar systems have been implemented into most capable servers so that monitoring of traffic on our services is possible. Additionally if something were to happen it allows to quicker identification of the source of the issue and remediate.

INDIVIDUAL REMIDATIONS AND HARDENING

AD:

- Secured ports and access with windows firewall
- Removed malicious scheduled tasks
- Removed malicious associated files and directories
- Setup secure connections to all necessary services on both ends

WWW:

- Implemented firewall rules on command line to ensure safety
- Removed unnecessary users
- Deleted and disabled possibly malicious files
- Removed unnecessary port access

LP:

- Secured ports and access with windows firewall
- Removed malicious scheduled tasks
- Removed a possible back door from the server
- Removed malicious associated files and directories
- Setup secure connections to all necessary services on both ends

WMS

- Implemented firewall rules on command line to ensure safety
- Removed unnecessary and hidden firewall rules
- Secured connection with AD
- Re-established backend functionality

DB

- Secured open ports and systems
- Removed malicious and unnecessary files
